

Puttable Bond and Vaulation

Summary

- ◆ Puttable Bond Definition
- ◆ The Advantages of Puttable Bonds
- ◆ Puttable Bond Payoffs
- ◆ Valuation Model Selection Criteria
- ◆ LGM Model
- ◆ LGM Assumption
- ◆ LGM calibration
- ◆ Valuation Implementation
- ◆ A real world example

Puttable Bond

Puttable Bond Definition

- ◆ A puttable bond is a bond in which the investor has the right to sell the bond back to the issuer at specified times (puttable dates) for a specified price (put price).
- ◆ At each puttable date prior to the bond maturity, the investor may sell the bond back to its issuer and get the investment money back.
- ◆ The underlying bonds can be fixed rate bonds or floating rate bonds.
- ◆ A puttable bond can therefore be considered a vanilla underlying bond with an embedded Bermudan style option.
- ◆ Puttable bonds protect investors. Therefore, a puttable bond normally pay the investor a lower coupon than a non-callable bond.

Puttable bond

Advantages of Puttable Bond

- ◆ Although a puttable bond is a lower income to the investor and an uncertainty to the issuer comparing to a regular bond, it is actually quite attractive to both issuers and investors.
- ◆ For investors, puttable bonds allow them to reduce interest costs at a future date should rate increase.
- ◆ For issuers, puttable bonds allow them to pay a lower interest rate of return until the bonds are sold back.
- ◆ If interest rates have increased since the issuer first issues the bond, the investor is like to put its current bond and reinvest it at a higher coupon.

Puttable Bond

Puttable Bond Payoffs

- ◆ At the bond maturity T , the payoff of a Puttable bond is given by

$$V_p(t) = \begin{cases} F + C & \text{if not pttd} \\ \max(P_p, F + C) & \text{if putted} \end{cases}$$

where F – the principal or face value; C – the coupon; P_p – the call price; $\min(x, y)$ – the minimum of x and y

- ◆ The payoff of the Puttable bond at any call date T_i can be expressed as

$$V_p(T_i) = \begin{cases} \bar{V}_{T_i} & \text{if not putted} \\ \max(P_p, \bar{V}_{T_i}) & \text{if putted} \end{cases}$$

where \bar{V}_{T_i} – continuation value at T_i

Model Selection Criteria

- ◆ Given the valuation complexity of puttable bonds, there is no closed form solution. Therefore, we need to select an interest rate term structure model and a numerical solution to price them numerically.
- ◆ The selection of interest rate term structure models
 - ◆ Popular interest rate term structure models:
Hull-White, Linear Gaussian Model (LGM), Quadratic Gaussian Model (QGM), Heath Jarrow Morton (HJM), Libor Market Model (LMM).
 - ◆ HJM and LMM are too complex.
 - ◆ Hull-White is inaccurate for computing sensitivities.
 - ◆ Therefore, we choose either LGM or QGM.

Model Selection Criteria (Cont)

- ◆ The selection of numeric approaches
 - ◆ After selecting a term structure model, we need to choose a numerical approach to approximate the underlying stochastic process of the model.
 - ◆ Commonly used numeric approaches are tree, partial differential equation (PDE), lattice and Monte Carlo simulation.
 - ◆ Tree and Monte Carlo are notorious for inaccuracy on sensitivity calculation.
 - ◆ Therefore, we choose either PDE or lattice.
- ◆ Our decision is to use LGM plus lattice.

Puttable Bond

LGM Model

- ◆ The dynamics

$$dX(t) = \alpha(t)dW$$

where X is the single state variable and W is the Wiener process.

- ◆ The numeraire is given by

$$N(t, X) = (H(t)X + 0.5H^2(t)\zeta(t))/D(t)$$

- ◆ The zero coupon bond price is

$$B(t, X; T) = D(T)\exp(-H(t)X - 0.5H^2(t)\zeta(t))$$

Puttable Bond

LGM Assumption

- ◆ The LGM model is mathematically equivalent to the Hull-White model but offers
 - ◆ Significant improvement of stability and accuracy for calibration.
 - ◆ Significant improvement of stability and accuracy for sensitivity calculation.
- ◆ The state variable is normally distributed under the appropriate measure.
- ◆ The LGM model has only one stochastic driver (one-factor), thus changes in rates are perfectly correlated.

Puttable Bond

LGM calibration

- ◆ Match today's curve
At time $t=0$, $X(0)=0$ and $H(0)=0$. Thus $Z(0,0;T)=D(T)$. In other words, the LGM automatically fits today's discount curve.
- ◆ Select a group of market swaptions.
- ◆ Solve parameters by minimizing the relative error between the market swaption prices and the LGM model swaption prices.

Puttable Bond

Valuation Implementation

- ◆ Calibrate the LGM model.
- ◆ Create the lattice based on the LGM: the grid range should cover at least 3 standard deviations.
- ◆ Calculate the payoff of the puttable bond at each final node.
- ◆ Conduct backward induction process iteratively rolling back from final dates until reaching the valuation date.
- ◆ Compare exercise values with intrinsic values at each exercise date.
- ◆ The value at the valuation date is the price of the puttable bond.

Puttable Bond

A real world example

Bond specification		Puttable schedule	
Buy Sell	Buy	Put Price	Notification Date
Calendar	NYC	100	1/26/2015
Coupon Type	Fixed	100	7/25/2018
Currency	USD		
First Coupon Date	7/30/2013		
Interest Accrual Date	1/30/2013		
Issue Date	1/30/2013		
Last Coupon Date	1/30/2018		
Maturity Date	7/30/2018		
Settlement Lag	1		
Face Value	100		
Pay Receive	Receive		
Day Count	dc30360		
Payment Frequency	6		
Coupon	0.01
